

RECKN

Keep assets native. Settle on proof.

An escrow that releases only when the work it was funded against can be re-executed and reproduced — and refunds the buyer when it cannot.

Reckn is **building the standard** for proof-driven settlement across execution environments. Agents may choose where work happens. Assets remain native. Reproducible execution decides payout.

Live on Arc testnet. psyto.github.io/reckn

THE CLAIM

**Nobody can move this
money.
Including us.**

The buyer locks USDC **in advance**, on the chain it
already lives on. A proof of an action **agreed
beforehand** releases it — or refunds it.

**Easy to say.
So don't take our word for it.**

Four checks. Ninety seconds. Nothing installed, no wallet.

CHECK ONE

A real proof that cannot take the money.

A valid Groth16 proof of a **different** execution,
submitted against a funded deal.

Nobody approves any of the three.

CHECK TWO

The code holding it, verified in your browser.

Your browser compares the deployed bytecode against
this source. Byte for byte.

CHECK THREE

Real money — and work proven on another chain.

SETTLEMENTS

4

Real USDC,
Arc testnet.

BY SOLANA
PROOFS**2**

One escrow,
two VMs.

TO DECIDE
ONE**<3¢**

From the
receipts.

Read off the chain by your browser, not by us.

WHY ARC

Arc is where the dollar stays.

The work happened on Solana. **The USDC never left Arc.** A conditional payment settles on a stablecoin-native rail without the asset being bridged anywhere.

Reckn removes a protocol-level judge. It does not erase issuer policy.

WHY TEMPO

Not just another EVM deployment.

Tempo has **no native gas token**. The escrow holds a stablecoin — and **the fee that releases it is paid in that same stablecoin**. Read off the receipt, not asserted.

Reckn removes a protocol-level judge. It does not erase issuer policy.

WHAT CROSSES THE BOUNDARY

RECKN / CROSS-VM SETTLEMENT

The proof crosses. The USDC does not.

A Solana computation is re-executed in a zkVM; Arc settles only from the verified result.

Scope: this proves the re-executed result matches the committed inputs. It does not yet prove those inputs came from Solana mainnet.

The proof crosses. The asset never does. · No bridge and no relayer has the authority to permit this payment.

CHECK FOUR — THE ONE NOBODY ELSE SHOWS YOU

What it does **not** prove.

Not	"Bridges are unnecessary."	It removes the bridge as the decider .
Not	"Liquidity is solved."	You still hold funds where you pay.
Not	"We prove Solana mainnet."	Consistency, not provenance .

Those three are **design** — they do not become true later.

Status, not claims: this is Arc **testnet**, and the thirty-day timeout refund is undemonstrated because a public chain cannot be fast-forwarded.

Try it at whatever depth you want.

- | | |
|--------------|--|
| 0 min | <code>npm run demo:local</code>
Release, refund, and a real proof of a different job refused — on a throwaway chain. |
| 2 min | <code>bash scripts/reckn terms</code>
Your transaction becomes the terms you would fund. Read-only, no key — on an endpoint that answers <code>eth_createAccessList</code> . |
| 5 min | Your wallet on Arc testnet.
Fund, preflight, watch a mismatched proof refused. |
| Later | Prove your step, settle, send the receipt.
Nobody outside has walked it yet. |

The local run is a local chain — not evidence about a public network.

TWO THINGS YOU CAN DO NOW

psyto.github.io/reckn
/money-shot.html

Now

An opinion **overruled by a replay**, then four settlements read off Arc.

Nothing installed, no wallet.

10 min

Clone it and run `npm run demo:local`.

A release, a refund, and a **real** proof of a different job refused.
